## Calculation of IBD probabilities

## David Evans and Stacey Cherny

## University of Oxford Wellcome Trust Centre for Human Genetics

## This Session

- IBD vs IBS
- Why is IBD important?
- Calculating IBD probabilities
- Lander-Green Algorithm (MERLIN)
- Single locus probabilities
- Hidden Markov Model
- Other ways of calculating IBD status
- Elston-Stewart Algorithm
- MCMC approaches
- MERLIN
- Practical Example
- IBD determination
- Information content mapping
- SNPs vs micro-satellite markers?

## Aim of Gene Mapping Experiments

. Identify variants that control interesting traits

- Susceptibility to human disease
- Phenotypic variation in the population
- The hypothesis
- Individuals sharing these variants will be more similar for traits they control
- The difficulty...
- Testing ~10 million variants is impractical...

## Identity-by-Descent (IBD)

- Two alleles are IBD if they are descended from the same ancestral allele
- If a stretch of chromosome is IBD among a set of individuals, ALL variants within that stretch will also be shared IBD (markers, QTLs, disease genes)
- Allows surveys of large amounts of variation even when a few polymorphisms measured

## A Segregating Disease Allele

All affected individuals IBD for disease causing mutation

## Segregating Chromosomes

Affected individuals tend to share adjacent areas of chromosome IBD

## Marker Shared Among Affecteds

" 4 " allele segregates with disease

## Why is IBD sharing important?

- IBD sharing forms the basis of nonparametric linkage statistics
- Affected relatives tend to share marker alleles close to the disease locus IBD more often than chance

## Linkage between QTL and marker

QTL
IBD 0

IBD 1

IBD 1

IBD 2

IBD 2

## NO Linkage between QTL and marker

Marker

IBD 1

IBD 2

## IBD vs IBS

Identical by Descent
and

Identical by State

Identical by state only

## Example: IBD in Siblings

Consider a mating between mother $\mathrm{AB} \times$ father CD :

|  | Sib1 |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | $\mathbf{A C}$ | $\mathbf{A D}$ | $\mathbf{B C}$ |
| $\mathbf{B D}$ |  |  |  |  |  |
| $\mathbf{S i b}$ | $\mathbf{A C}$ | 2 | 1 | 1 | 0 |
|  | $\mathbf{A D}$ | 1 | 2 | 0 | 1 |
|  | BC | 1 | 0 | 2 | 1 |
|  | $\mathbf{B D}$ | 0 | 1 | 1 | 2 |

$$
\text { IBD } 0: 1: 2=25 \%: 50 \%: 25 \%
$$

## IBD can be trivial...

## Two Other Simple Cases...

## A little more complicated...

## And even more complicated...

## Bayes Theorem

$$
\begin{aligned}
P\left(A_{i} \mid B\right) & =\frac{P\left(A_{i}, B\right)}{P(B)} \\
& =\frac{P\left(A_{i}\right) P\left(B \mid A_{i}\right)}{P(B)} \\
& =\frac{P\left(A_{i}\right) P\left(B \mid A_{i}\right)}{\sum_{j} P\left(A_{j}\right) P\left(B \mid A_{j}\right)}
\end{aligned}
$$

## Bayes Theorem for IBD Probabilities

$$
\begin{aligned}
P(I B D=i \mid G) & =\frac{\mathrm{P}(\mathrm{IBD}=i, G)}{P(G)} \\
& =\frac{P(I B D=i) P(G \mid I B D=i)}{P(G)} \\
& =\frac{P(I B D=i) P(G \mid I B D=i)}{\sum_{j} P(I B D=j) P(G \mid I B D=j)}
\end{aligned}
$$

## P(Marker Genotype|IBD State)

| Sib 1 | Sib 2 | P (observing genotypes $/ k$ alleles IBD) |  |  |
| :--- | :--- | :--- | :--- | :--- |
|  |  | $k=0$ | $k=1$ | $k=2$ |
| $\mathrm{~A}_{1} \mathrm{~A}_{1}$ | $\mathrm{~A}_{1} \mathrm{~A}_{1}$ | $p_{1}{ }^{4}$ | $p_{1}{ }^{3}$ | $p_{1}{ }^{2}$ |
| $\mathrm{~A}_{1} \mathrm{~A}_{1}$ | $\mathrm{~A}_{1} \mathrm{~A}_{2}$ | $2 p_{1}{ }^{3} p_{2}$ | $p_{1}{ }^{2} p_{2}$ | 0 |
| $\mathrm{~A}_{1} \mathrm{~A}_{1}$ | $\mathrm{~A}_{2} \mathrm{~A}_{2}$ | $p_{1}{ }^{2} p_{2}{ }^{2}$ | 0 | 0 |
| $\mathrm{~A}_{1} \mathrm{~A}_{2}$ | $\mathrm{~A}_{1} \mathrm{~A}_{1}$ | $2 p_{1}{ }^{3} p_{2}$ | $p_{1}{ }^{2} p_{2}$ | 0 |
| $\mathrm{~A}_{1} \mathrm{~A}_{2}$ | $\mathrm{~A}_{1} \mathrm{~A}_{2}$ | $4 p_{1}{ }^{2} p_{2}{ }^{2}$ | $p_{1} p_{2}$ | $2 p_{1} p_{2}$ |
| $\mathrm{~A}_{1} \mathrm{~A}_{2}$ | $\mathrm{~A}_{2} \mathrm{~A}_{2}$ | $2 p_{1} p_{2}{ }^{3}$ | $p_{1} p_{2}{ }^{2}$ | 0 |
| $\mathrm{~A}_{2} \mathrm{~A}_{2}$ | $\mathrm{~A}_{1} \mathrm{~A}_{1}$ | $p_{1}{ }^{2} p_{2}{ }^{2}$ | 0 | 0 |
| $\mathrm{~A}_{2} \mathrm{~A}_{2}$ | $\mathrm{~A}_{1} \mathrm{~A}_{2}$ | $2 p_{1} p_{2}{ }^{3}$ | $p_{1} p_{2}{ }^{2}$ | 0 |
| $\mathrm{~A}_{2} \mathrm{~A}_{2}$ | $\mathrm{~A}_{2} \mathrm{~A}_{2}$ | $p_{2}{ }^{4}$ | $p_{2}{ }^{3}$ | $p_{2}{ }^{2}$ |

## Worked Example <br> 

## Worked Example

$$
\begin{aligned}
& p_{1}=0.5 \\
& P(G \mid I B D=0)=p_{1}^{4}=1 / 16 \\
& P(G \mid I B D=1)=p_{1}^{3}=1 / 8 \\
& P(G \mid I B D=2)=p_{1}^{2}=1 / 4 \\
& P(G)=1 / 4 p_{1}^{4}+1 / 2 p_{1}^{3}+1 / 4 p_{1}^{2}=9 / 64 \\
& P(I B D=0 \mid G)=\frac{1 / 4 p_{1}^{4}}{P(G)}=1 / 9 \\
& P(I B D=1 \mid G)=\frac{1 / 2 p_{1}^{3}}{P(G)}=4 / 9 \\
& P(I B D=2 \mid G)=\frac{1 / 4 p_{1}^{2}}{P(G)}=4 / 9
\end{aligned}
$$

For ANY PEDIGREE the inheritance pattern at every point in the genome can be completely described by a binary inheritance vector:

$$
\mathrm{v}(\mathrm{x})=\left(p_{1}, m_{1}, p_{2}, m_{2}, \ldots, p_{n}, m_{n}\right)
$$

whose coordinates describe the outcome of the 2 n paternal and maternal meioses giving rise to the $n$ non-founders in the pedigree
$p_{i}\left(m_{i}\right)$ is 0 if the grandpaternal allele transmitted $p_{i}\left(m_{i}\right)$ is 1 if the grandmaternal allele is transmitted

## Inheritance Vector

In practice, it is not possible to determine the true inheritance vector at every point in the genome, rather we represent partial information as a probability distribution over the $2^{2 \mathrm{n}}$ possible inheritance vectors

| Inheritance vector | Prior | Posterior |
| :--- | :--- | :--- |
| $--------------------------------------------1 / 8$ |  |  |
| 0000 | $1 / 16$ | $1 / 8$ |
| 0001 | $1 / 16$ | 0 |
| 0010 | $1 / 16$ | 0 |
| 0011 | $1 / 16$ | $1 / 8$ |
| 0100 | $1 / 16$ | $1 / 8$ |
| 0101 | $1 / 16$ | 0 |
| 0110 | $1 / 16$ | 0 |
| 0111 | $1 / 16$ | $1 / 8$ |
| 1000 | $1 / 16$ | $1 / 8$ |
| 1001 | $1 / 16$ | 0 |
| 1010 | $1 / 16$ | 0 |
| 1011 | $1 / 16$ | $1 / 8$ |
| 1100 | $1 / 16$ | $1 / 8$ |
| 1101 | $1 / 16$ | 0 |
| 1110 | $1 / 16$ | 0 |

## Computer Representation

- Define inheritance vector $\mathbf{v}_{\ell}$
- Each inheritance vector indexed by a different memory location
- Likelihood for each gene flow pattern
- Conditional on observed genotypes at location $\ell$
- $2^{2 n}$ elements !!!
- At each marker location $\ell$

a) bit-indexed array

| 0000 | 001 | 0010 | 011 | 00 | 101 | 0110 | 0111 | 1000 | 01 | 1010 | 1011 | 00 | 101 | 110 | 1111 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $L_{4}$ | $\mathrm{L}_{2}$ | $L_{1}$ | $\mathrm{L}_{2}$ | $\bigcirc$ | $\bigcirc$ | $\bigcirc$ | $\bigcirc$ | $L_{1}$ | $\mathrm{L}_{2}$ | $L_{1}$ | $\mathrm{L}_{2}$ | $\bigcirc$ | $\bigcirc$ | $\bigcirc$ | - |

b) packed tree

c) sparse tree

Abecasis et al (2002) Nat Genet 30:97-101

## Multipoint IBD

- IBD status may not be able to be ascertained with certainty because e.g. the mating is not informative, parental information is not available
- IBD information at uninformative loci can be made more precise by examining nearby linked loci

## Multipoint IBD

$\operatorname{IBD}=0$

b/d
$1 / 2$
$\mathrm{IBD}=0$ or $\mathrm{IBD}=1 ?$

## Complexity of the Problem in Larger Pedigrees

- $2 n$ meioses in pedigree with $n$ nonfounders
- Each meiosis has 2 possible outcomes
- Therefore $2^{2 n}$ possibilities for each locus
- For each genetic locus
- One location for each of $m$ genetic markers
- Distinct, non-independent meiotic outcomes
- Up to $4^{n m}$ distinct outcomes!!!

## Example: Sib-pair Genotyped at 10 Markers

$\left(2^{2 \times n}\right)^{m}=\left(2^{2 \times 2}\right)^{10}=10^{12}$ possible paths !!!

## Lander-Green Algorithm

- The inheritance vector at a locus is conditionally independent of the inheritance vectors at all preceding loci given the inheritance vector at the immediately preceding locus ("Hidden Markov chain")
- The conditional probability of an inheritance vector $v_{i+1}$ at locus $i+1$, given the inheritance vector $v_{i}$ at locus $i$ is $\theta_{j}^{j}\left(1-\theta_{i}\right)^{2 n-j}$ where $\theta$ is the recombination fraction and $j$ is the number of changes in elements of the inheritance vector ("transition probabilities")

Example:

| Locus 1 | Locus 2 |
| :---: | :---: |
| [0000] | [0001] |

Conditional probability $=(1-\theta)^{3} \theta$

$Q_{i}=$| $P[0000]$ | 0 | 0 | 0 |
| :---: | :---: | :---: | :---: |
| 0 | $P[0001]$ | 0 | 0 |
| 0 | 0 | $\cdots$ | 0 |
| 0 | 0 | 0 | $P[1111]$ |

$2^{2 n} \times 2^{2 n}$ diagonal matrix of single locus probabilities at locus i

$2^{2 n} \times 2^{2 n}$ matrix of transitional probabilities between locus $i$ and locus i+1
$\sim 10 \times\left(2^{2 \times 2}\right)^{2}$ operations $=2560$ for this case !!!

## $P(I B D)=2$ at Marker Three

## $\mathrm{P}(\mathrm{IBD})=2$ at arbitrary position on the chromosome

## Further speedups...

- Trees summarize redundant information
- Portions of inheritance vector that are repeated
- Portions of inheritance vector that are constant or zero
- Use sparse-matrix by vector multiplication
- Regularities in transition matrices
- Use symmetries in divide and conquer algorithm (Idury \& Elston, 1997)

## Lander-Green Algorithm Summary

- Factorize likelihood by marker
- Complexity $\propto m \cdot e^{n}$
- Large number of markers (e.g. dense SNP data)
- Relatively small pedigrees
- MERLIN, GENEHUNTER, ALLEGRO etc

## Elston-Stewart Algorithm

- Factorize likelihood by individual
- Complexity $\propto n^{\prime} \cdot e^{m}$
- Small number of markers
- Large pedigrees
- With little inbreeding
- VITESSE etc

## Other methods

- Number of MCMC methods proposed
- ~Linear on \# markers
- ~Linear on \# people
- Hard to guarantee convergence on very large datasets
- Many widely separated local minima
- E.g. SIMWALK, LOKI

## MERLIN-- Multipoint Engine for Rapid Likelihood Inference

## Capabilities

- Linkage Analysis
- NPL and K\&C LOD
- Variance Components
- Haplotypes
- Most likely
- Sampling
- All
- IBD and info content
- Error Detection
- Most SNP typing errors are Mendelian consistent
- Recombination
- No. of recombinants per family per interval can be controlled
- Simulation

## MERLIN Website

- Reference
- FAQ
- Source
- Tutorial
- Linkage
- Haplotyping
- Simulation
- Error detection
- IBD calculation
- Binaries

## Test Case Pedigrees

## Timings - Marker Locations

|  | Top Generation Genotyped |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\mathrm{A}(\mathrm{x} 1000)$ | B C <br> 37 s 18 m 16 s |  | D |
| Genehunter | 38s |  |  |  |
| Allegro | 18s | 2m17s | h54m13s |  |
| Merlin | 11s | 18s | 13m55s | * |
|  | Top Generation Not Genotyped |  |  |  |
|  | A (x1000) | B | C | D |
| Genehunter | 45s | 1m54s | * |  |
| Allegro | 18s | 1m08s | h12m38s | * |
| Merlin | 13s | 25s | 15m50s | * |

## Intuition: Approximate Sparse T

- Dense maps, closely spaced markers
- Small recombination fractions $\theta$
- Reasonable to set $\theta^{k}$ with zero
- Produces a very sparse transition matrix
- Consider only elements of $\mathbf{V}$ separated by <k recombination events
- At consecutive locations

## Additional Speedup...

|  | Time | Memory |
| :---: | ---: | ---: |
| Exact | 40 s | 100 MB |

| No recombination | $<1 \mathrm{~s}$ | 4 MB |
| :--- | ---: | ---: |
| $\leq 1$ recombinant | 2 s | 17 MB |
| $\leq 2$ recombinants | 15 s | 54 MB |

Genehunter $2.1 \quad 16 \mathrm{~min} \quad 1024 \mathrm{MB}$

Keavney et al (1998) ACE data, 10 SNPs within gene, 4-18 individuals per family

## Input Files

- Pedigree File
- Relationships
- Genotype data
- Phenotype data
- Data File
- Describes contents of pedigree file
- Map File
- Records location of genetic markers

## Example Pedigree File

Encodes family relationships, marker and phenotype information

## Example Data File

<contents of example.dat>
T some_trait_of_interest
M some_marker
M another_marker
<end of example.dat>

Provides information necessary to decode pedigree file

## Data File Field Codes

| Code | Description |
| :--- | :--- |
| M | Marker Genotype |
| A | Affection Status. |
| T | Quantitative Trait. |
| C | Covariate. |
| Z | Zygosity. |
|  |  |

## Example Map File

<contents of example.map>
CHROMOSOME MARKER POSITION
2
D2S160 160.0
D2S308 165.0
<end of example.map>

Indicates location of individual markers, necessary to derive recombination fractions between them

## Worked Example

$$
\begin{aligned}
& p_{1}=0.5 \\
& P(I B D=0 \mid G)=1 / 9 \\
& P(I B D=1 \mid G)=4 / 9 \\
& P(I B D=2 \mid G)=4 / 9
\end{aligned}
$$

merlin -d example.dat -p example.ped -m example.map --ibd

## Application: Information Content Mapping

- Information content: Provides a measure of how well a marker set approaches the goal of completely determining the inheritance outcome
- Based on concept of entropy
- $E=-\Sigma P_{i} \log _{2} P_{i} \quad$ where $P_{i}$ is probability of the th outcome
- $\mathrm{I}_{\mathrm{E}}(\mathrm{x})=1-\mathrm{E}(\mathrm{x}) / \mathrm{E}_{0}$
- Always lies between 0 and 1
- Does not depend on test for linkage
- Scales linearly with power

## Application: Information Content Mapping

- Simulations (sib-pairs with/out parental genotypes)
- 1 micro-satellite per 10 cM (ABI)
- 1 microsatellite per 3cM (deCODE)
- 1 SNP per 0.5cM (Illumina)
- 1 SNP per 0.2 cM (Affymetrix)
- Which panel performs best in terms of extracting marker information?
- Do the results depend upon the presence of parental genotypes?
merlin -d file.dat -p file.ped -m file.map --information --step 1 --markerNames

## SNPs vs Microsatellites with parents

## SNPs vs Microsatellites without parents
